(54) Title: FRUIT RIPENING-RELATED GENES

#### (57) Abstract

vector for in use genetic transformation of strawberry cells comprises promoter sequence, a regulation sequence and a transcription termination sequence, in which the regulation sequence comprises the coding region, or a fragment of at least 10 bases thereof, of a strawberry protein selected from O-methyl transferase, acyl carrier protein (ACP), elongation factor, auxin-induced cysteine(thiol) proteinase, cellulase, starch phosphorylase, pyruvate decarboxylase, chalcone reductase. protein kinase, auxin-related gene, transporter, meristem pattern gene, or selected from a strawberry protein with homology to transcribed sequence accession T45086. transcribed sequence accession number L36159 or transcribed sequence accession number T45902, or selected from a strawberry protein of unknown homology encoded by one of the StrawRipe sequences A to K.

## FRUIT RIPENING-RELATED GENES

This invention relates generally to the modification of a plant phenotype by the regulation of plant gene expression. More specifically it relates to the control of fruit ripening by control of one or more than one gene which is known to be implicated in that process.

#### BACKGROUND OF THE INVENTION

Two principal methods for the control of expression are known. These are referred to in the art as "antisense downregulation" and "sense downregulation" or "cosuppression". Both of these methods lead to an inhibition of expression of the target gene. Overexpression is achieved by insertion of one or more than one extra copies of the selected gene. Other lesser used methods involve modification of the genetic control elements, the promoter and control sequences, to achieve greater or lesser expression of an inserted gene.

In antisense downregulation, a DNA which is complementary to all or part of the target gene is inserted into the genome in reverse orientation and without its translation initiation signal. The simplest theory is that such an antisense gene, which is transcribable but not translatable, produces mRNA which is complementary in sequence to mRNA product transcribed from the endogenous gene: that antisense mRNA then binds with the naturally produced "sense" mRNA to form a duplex which inhibits translation of the natural mRNA to protein. It is not necessary that the inserted antisense gene be equal in length to the endogenous gene sequence: a fragment is

sufficient. The size of the fragment does not appear to be particularly important. Fragments as small as 40 or so nucleotides have been reported to be effective. Generally somewhere in the region of 50 nucleotides is accepted as sufficient to obtain the inhibitory effect. However, it has to be said that fewer nucleotides may very well work: a greater number, up to the equivalent of full length, will certainly work. It is usual simply to use a fragment length for which there is a convenient restriction enzyme cleavage site somewhere downstream of fifty nucleotides. The fact that only a fragment of the gene is required means that not all of the gene need be sequenced. It also means that commonly a cDNA will suffice, obviating the need to isolate the full genomic sequence.

The antisense fragment does not have to be precisely the same as the endogenous complementary strand of the target gene. There simply has to be sufficient sequence similarity to achieve inhibition of the target gene. This is an important feature of antisense technology as it permits the use of a sequence which has been derived from one plant species to be effective in another and obviates the need to construct antisense vectors for each individual species of interest. Although sequences isolated from one species may be effective in another, it is not infrequent to find exceptions where the degree of sequence similarity between one species and the other is insufficient for the effect to be obtained. In such cases, it may be necessary to isolate the species-specific homologue.

Antisense downregulation technology is well-established in the art. It is the subject of several textbooks and many hundreds of journal publications. The principal patent reference is European Patent No. 240,208 in the name of Calgene Inc. There is no reason to doubt the operability of antisense technology. It is well-established, used routinely in laboratories around the world and products in which it is used are on the market.

Both overexpression and downregulation are achieved by "sense" technology. If a full length copy of the target gene is inserted into the genome then a range of phenotypes is obtained, some overexpressing the target gene, some underexpressing. A population of plants produced by this method may then be screened and individual phenotypes isolated. As with antisense, the inserted sequence is lacking in a translation initiation signal. Another similarity with antisense is that the inserted sequence need not be a full length copy. Indeed, it has been found that the distribution of over-and under-expressing phenotypes is skewed in favour of underexpression and this is advantageous when gene inhibition is the desired effect. For overexpression, it is preferable that the inserted copy gene retain its translation initiation codon. The principal patent reference on cosuppression is European Patent 465,572 in the name of DNA Plant Technology Inc. There is no reason to doubt the operability of sense/cosuppression technology. It is well established, used routinely in laboratories around the world and products in which it is used are on the market.

Sense and antisense gene regulation is reviewed by Bird and Ray in

Biotechnology and Genetic Engineering Reviews 9: 207-227 (1991). The use of these techniques to control selected genes in tomato has been described by Gray et al., Plant Molecular Biology, 19: 69-87 (1992).

Gene control by any of the methods described requires insertion of the sense or antisense sequence, with appropriate promoters and termination sequences containing polyadenylation signals, into the genome of the target plant species by transformation, follow by regeneration of the transformants into whole plants. It is probably fair to say that transformation methods exist for most plant species or can be obtained by adaptation of available methods.

For dicotyledonous plants the most widely used method is Agrobacteriummediated transformation. This is the best known, most widely studied and, therefore, best understood of all transformation methods. The rhizobacterium Agrobacterium tumefaciens, or the related Agrobacterium rhizogenes, contain certain plasmids which, in nature, cause the formation of disease symptoms, crown gall or hairy root tumours, in plants which are infected by the bacterium. Part of the mechanism employed by Agrobacterium in pathogenesis is that a section of plasmid DNA which is bounded by right and left border regions is transferred stably into the genome of the infected plant. Therefore, if foreign DNA is inserted into the so-called "transfer" region (T-region) in substitution for the genes normally present therein, that foreign gene will be transferred into the plant genome. There are many hundreds of references in the journal literature, in textbooks and in patents and the methodology is well-established. Agrobacterium-mediated transformation of the cultivated strawberry (Fragaria x ananassa Duch. is described in Plant Science, 69, 79-94 (1990).

The effectiveness of Agrobacterium is restricted to the host range of the microorganism and is thus restricted more or less to dicotyledonous plant species. In
general monocotyledonous species, which include the important cereal crops, are not
amenable to transformation by the Agrobacterium method. Various methods for the
direct insertion of DNA into the nucleus of monocotyledon cells are known.

In the ballistic method, microparticles of dense material, usually gold or tungsten, are fired at high velocity at the target cells where they penetrate the cells, opening an aperture in the cell wall through which DNA may enter. The DNA may be coated on to the microparticles or may be added to the culture medium.

In microinjection, the DNA is inserted by injection into individual cells via an ultrafine hollow needle.

Another method, applicable to both monocotyledons and dicotyledons, involves creating a suspension of the target cells in a liquid, adding microscopic needle-like material, such as silicon carbide or silicon nitride " whiskers", and agitating so that the cells and whiskers collide and DNA present in the liquid enters the cell.

In summary, then, the requirements for both sense and antisense technology are known and the methods by which the required sequences may be introduced are known. What remains, then is to identify genes whose regulation will be expected to have a desired effect, isolate them or isolate a fragment of sufficiently effective length, construct a chimeric gene in which the effective fragment is inserted between promoter and termination signals, and insert the construct into cells of the target plant species by transformation. Whole plants may then be regenerated from the transformed cells.

This invention is concerned with the control of ripening in fruit, and the particular interest here is in strawberries.

The interest in controlling the ripening process is to improve the flavour and/or texture of the fruit, both characters being largely affected by the ripening process.

Sugars are the most important soluble component of the flavour. Some 99% of the soluble sugars in strawberry are accounted for by sucrose, glucose and fructose, the amount of these sugars being affected by the season but their relative proportions are largely unaffected.

There is little information in the literature on the metabolic pathways involved in the synthesis of sugars in strawberry. It is known, however that sugars are synthesised during the ripening of the fruit.

The changes in gene expression during strawberry fruit ripening and their regulation by auxin have been described in Planta 194: 62-68 (1994)

**OBJECT OF THE INVENTION** 

An object of the present invention is to provide DNA sequences enabling the construction of vectors suitable for genetic transformation of strawberry plants, with a view to control of the ripening process in strawberry fruit.

### SUMMARY OF THE INVENTION

According to the present invention there is provided a vector for use in the genetic transformation of strawberry cells, comprising a promoter sequence, a regulation sequence and a transcription termination sequence, in which the regulation sequence comprises the coding region, or a fragment of at least 10 bases thereof, of a strawberry protein selected from O-methyl transferase, acyl carrier protein (ACP), elongation factor, auxin-induced gene, cysteine(thiol) proteinase, cellulase, starch phosphorylase, pyruvate decarboxylase, chalcone reductase, protein kinase, auxin-related gene, sucrose transporter, meristem pattern gene, or selected from a strawberry protein with homology to transcribed sequence accession number T45086, transcribed sequence accession number L36159 or transcribed sequence accession number T45902, or selected from a strawberry protein of unknown homology encoded by one of the StrawRipe sequences A to K.

The gene regulation sequence may be in the same or antisense orientation as the endogenous target gene. It may also be of partial or full sequence length. The invention further contemplates the overexpression of one or more of the genes by inserting into the strawberry genome one or more than one extra copy thereof.

The invention also provides a gene regulation sequence which comprises the coding region, or a fragment of at least 10 bases thereof, of a strawberry protein selected from O-methyl transferase, acyl carrier protein (ACP), elongation factor, auxin-induced gene, cysteine(thiol) proteinase, cellulase, starch phosphorylase, pyruvate decarboxylase, chalcone reductase, protein kinase, auxin-related gene, sucrose

transporter, meristem pattern gene, or selected from a strawberry protein with homology to transcribed sequence accession number T45086, transcribed sequence accession number L36159 or transcribed sequence accession number T45902, or selected from a strawberry protein of unknown homology encoded by one of the StrawRipe sequences A to K.

The sequences of this invention can also be used as probes for isolation of similar sequences from the strawberry genome:

The invention also provides a strawberry plant and propagating material thereof which contains a vector of this invention.

Further according to the invention, there is provided a method for altering the phenotype of strawberry plants, with the aim of controlling the ripening of strawberry fruit, comprising inserting into the genome of the cell of a strawberry plant a gene regulation vector of this invention.

In this way, the invention further provides genetically modified strawberry plants, propagation material and strawberry fruit.

#### PREFERRED EMBODIMENTS

In the present invention, the regulation sequence comprises the coding region, or a fragment of at least 10 bases thereof, of a strawberry protein. The strawberry protein is selected from O-methyl transferase, acyl carrier protein (ACP), elongation factor, auxin-induced gene, cysteine(thiol) proteinase, cellulase, starch phosphorylase, pyruvate decarboxylase, chalcone reductase, protein kinase, auxin-related gene, sucrose transporter, meristem pattern gene, or selected from a strawberry protein with homology to transcribed sequence accession number T45086, transcribed sequence

accession number L36159 or transcribed sequence accession number T45902, or selected from a strawberry protein of unknown homology encoded by one of the StrawRipe sequences A to K.

Examples of suitable regulation sequences are SEQ ID NO:1: to SEQ ID NO:27:, also referred to herein as Sequences 1 to 27. Related sequences taken from the priority documents of the present PCT application are given in SEQ ID NO:28: to SEQ ID NO:38:.

The gene regulation sequences of the invention may be synthesised from the sequence information given or may be isolated from a library. To assist isolation Zeneca Limited have deposited with the National Collection of Industrial & Marine Bacteria, St. Machar Drive, Aberdeen, UK, a cDNA library of strawberry ripening genes. The library was deposited on 15th November 1994 under the Budapest Treaty and has the Accession Number NCIMB 40690.

Thus, this invention is based on the identification of genes which encode proteins implicated in strawberry ripening-related processes. DNA sequences which encode these proteins have been cloned and some have been characterised. The DNA sequences may be used to modify plants with the goal of modifying the ripening characteristics of fruit.

By virtue of this invention strawberry plants can be generated which, amongst other phenotypic modifications, may have one or more of the following fruit characteristics:

improved resistance to damage during harvest, packaging and transportation due to slowing of the ripening and over-ripening processes;

longer shelf life and better storage characteristics due to reduced activity of degradative pathways (e.g. cell wall hydrolysis).

improved processing characteristics due to changed activity of proteins/enzymes contributing to factors such as: viscosity, solids, pH, elasticity;

improved flavour and aroma at the point of sale due to modification of the sugar/acid balance and other flavour and aroma components responsible for characteristics of the ripe fruit;

modified colour due to changes in activity of enzymes involved in the pathways of pigment biosynthesis (e.g. lycopene, β-carotene, chalcones and anthocyanins), increased resistance to post-harvest pathogens such as fungi.

The activity of the ripening-related proteins may be either increased or reduced depending on the characteristics desired for the modified plant part (fruit, leaf, flower, etc). The levels of protein may be increased; for example, by incorporation of additional genes. The additional genes may be designed to give either the same or different spatial and temporal patterns of expression in the fruit. "Antisense" or "partial sense" or other techniques may be used to reduce the expression of ripening-related protein.

The activity of each ripening-related protein or enzyme may be modified either individually or in combination with modification of the activity of one or more other ripening-related proteins/enzymes. In addition, the activities of the ripening-related proteins/enzymes may be modified in combination with modification of the activity of other enzymes involved in fruit ripening or related processes.

DNA constructs according to the invention may comprise a base sequence at least 10 bases (preferably at least 35 bases) in length for transcription into RNA.

There is no theoretical upper limit to the base sequence - it may be as long as the relevant mRNA produced by the cell - but for convenience it will generally be found suitable to use sequences between 100 and 1000 bases in length. The preparation of such constructs is described in more detail below.

As a source of the DNA base sequence for transcription, a suitable cDNA or genomic DNA or synthetic polynucleotide may be used. The isolation of suitable ripening-related sequences is described above; it is convenient to use DNA sequences derived from the ripening-related clones deposited at NCIMB in Aberdeen. Sequences coding for the whole, or substantially the whole, of the appropriate ripening-related protein may thus be obtained. Suitable lengths of this DNA sequence may be cut out for use by means of restriction enzymes. When using genomic DNA as the source of a base sequence for transcription it is possible to use either intron or exon regions or a combination of both.

In a variation of the vector of this invention the regulation sequence varies from Sequences 1 to 27 but retains sufficient similarity to be effective in gene regulation. Thus, the regulatory gene may be a homologue of a gene of Sequence 1 to 27 which has been obtained from a strawberry plant.

To obtain constructs suitable for expression of the appropriate ripening-related sequence in plant cells, the cDNA sequence as found in one of the strawberry plasmids or the gene sequence as found in the chromosome of the strawberry plant may be used. Recombinant DNA constructs may be made using standard techniques. For example, the DNA sequence for transcription may be obtained by treating a vector containing said sequence with restriction enzymes to cut out the appropriate segment. The DNA sequence for transcription may also be generated by annealing and ligating synthetic oligonucleotides or by using synthetic oligonucleotides in a polymerase chain reaction (PCR) to give suitable restriction sites at each end. The DNA sequence is then cloned into a vector containing upstream promoter and downstream terminator sequences. If

antisense DNA is required, the cloning is carried out so that the cut DNA sequence is inverted with respect to its orientation in the strand from which it was cut.

Promoters suitable for use in constructs of the invention may be any suitable promoters which are known to be effective in driving expression of foreign genes in plants, for example the promoters may be those which are isolatable from the genomic version of the cDNAs of the invention.

In a construct expressing antisense RNA, the strand that was formerly the template strand becomes the coding strand, and vice versa. The construct will thus encode RNA in a base sequence which is complementary to part or all of the sequence of the ripening-related RNA. Thus the two RNA strands are complementary not only in their base sequence but also in their orientations (5' to 3')

In a construct expressing sense RNA, the template and coding strands retain the assignments and orientations of the original plant gene. Constructs expressing sense, RNA encode RNA with a base sequence which is homologous to part or all of the sequence of the mRNA. In constructs which express the functional ripening-related protein, the whole of the coding region of the gene is linked to transcriptional control sequences capable of expression in plants.

For example, constructs according to the present invention may be made as follows. A suitable vector containing the desired base sequence for transcription is treated with restriction enzymes to cut the sequence out. The DNA strand so obtained is cloned (if desired, in reverse orientation) into a second vector containing the desired promoter sequence and the desired terminator sequence. Suitable promoters include the 35S cauliflower mosaic virus promoter, the polyubiquitin promoter and the tomato polygalacturonase gene promoter sequence (Bird et al. 1988, Plant Molecular Biology, 11:651-662) or other developmentally regulated fruit promoters. Suitable terminator

sequences include that of the Agrobacterium tumefaciens nopaline synthase gene (the nos 3' end).

The transcriptional initiation region (or promoter) operative in plants may be a constitutive promoter (such as the 35S cauliflower mosaic virus promoter) or an inducible or developmentally regulated promoter (such as fruit-specific promoters), as circumstances require. For example, it may be desirable to modify ripening-related protein activity only during fruit development and/or ripening. Use of a constitutive promoter will tend to affect ripening-related protein levels and functions in all parts of the plant, while use of a tissue specific promoter allows more selective control of gene expression and affected functions. Thus in applying the invention it may be found convenient to use a promoter that will give expression during fruit development and/or ripening. Thus the antisense or sense RNA is produced only in the organ in which its action is required and/or only at the time required. Fruit development and/or ripening-specific promoters that could be used include the ripening-enhanced polygacturonase promoter (PCT/WO 92/08798), the E8 promoter (Diekman & Fischer, 1988, EMBO, 7:3315-3320), the fruit specific 2AII promoter (Pear et al, 1989, Plant Molecular Biology, 13:639-651), the histidine decarboxylase promoter (HDC, Sibia) and the phytoene synthase promoter.

Ripening-related protein or enzyme activity (and hence ripening-related processes and fruit ripening characteristics) may be modified to a greater or lesser extent by controlling the degree of the appropriate ripening-related protein's sense or antisense mRNA production in the plant cells. This may be done by suitable choice of promoter sequences, or by selecting the number of copies or the site of integration of the DNA sequences that are introduced into the plant genome. For example, the DNA construct may include more than one DNA sequence encoding the ripening-related protein or more than one recombinant construct may be transformed into each plant cell.

Ţ

The activity of each ripening-related protein may be separately modified by transformation with a suitable DNA construct comprising a ripening-related sequence. In addition, the activity of two or more ripening-related proteins may be simultaneously modified by transforming a cell with two or more separate constructs. Alternatively, a plant cell may be transformed with a single DNA construct comprising both a first ripening-related sequence and a second ripening-related sequence.

It is also possible to modify the activity of the ripening-related protein(s) while also modifying the activity of one or more other enzymes. The other enzymes may be involved in cell metabolism or in fruit development and ripening. Cell wall metabolising enzymes that may be modified in combination with a ripening-related protein include but are not limited to: pectin esterase, polygalacturonase, β-galactanase, β-glucanase. Other enzymes involved in fruit development and ripening that may be modified in combination with a ripening-related protein include but are not limited to: ethylene biosynthetic enzymes, carotenoid biosynthetic enzymes including phytoene synthase, carbohydrate metabolism enzymes including invertase.

Several methods are available for modification of the activity of the ripening-related protein(s) in combination with other enzymes. For example, a first plant may be individually transformed with a ripening-related gene construct and then crossed with a second plant which has been individually transformed with a construct encoding another enzyme. As a further example, plants may be either consecutively or co-transformed with ripening-related constructs and with appropriate constructs for modification of the activity of the other enzyme(s). An alternative example is plant transformation with a ripening-related construct which itself contains an additional gene for modification of the activity of the other enzyme(s). The ripening-related gene constructs may contain sequences of DNA for regulation of the expression of the other enzyme(s) located adjacent to the ripening-related sequences. These additional sequences may be in either sense or antisense orientation as described in PCT/WO 93/23551 (single construct having distinct DNA regions homologous to different target

genes) By using such methods, the benefits of modifying the activity of the ripening-related proteins may be combined with the benefits of modifying the activity of other enzymes:

A DNA construct of the invention is transformed into a target plant cell. The target plant cell may be part of a whole plant or may be an isolated cell or part of a tissue which may be regenerated into a whole plant. For any particular plant cell, the ripening-related sequence used in the transformation construct may be derived from the same plant species, or may be derived from any other plant species (as there will be sufficient sequence similarity to allow modification of related isoenzyme gene expression).

Transgenic plants and their progeny may be used in standard breeding programmes, resulting in improved plant lines having the desired characteristics For example, fruit-bearing plants expressing a ripening-related construct according to the invention may be incorporated into a breeding programme to alter fruit-ripening characteristics and/or fruit quality. Such altered fruit may be easily derived from elite lines which already possess a range of advantageous traits after a substantial breeding programme: these elite lines may be further improved by modifying the expression of a single targeted ripening-related protein/enzyme to give the fruit a specific desired property.

By transforming plants with DNA constructs according to the invention, it is possible to produce plants having an altered (increased or reduced) level of expression of one or more ripening-related proteins, resulting from the presence in the plant genome of DNA capable of generating sense or antisense RNA homologous or complementary to the RNA that generates such ripening-related proteins. For fruit-bearing plants, fruit may be obtained by growing and cropping using conventional methods. Seeds may be obtained from such fruit by conventional methods (for example, tomato seeds are separated from the pulp of the ripe fruit and dried, following

which they may be stored for one or more seasons). Fertile seed derived from the genetically modified fruit may be grown to produce further similar modified plants and fruit.

The fruit derived from genetically modified plants and their progeny may be sold for immediate consumption, raw or cooked, or processed by canning or conversion to soup, sauce or paste. Equally, they may be used to provide seeds according to the invention.

The genetically modified plants (transformed plants and their progeny) may be heterozygous for the ripening-related DNA constructs. The seeds obtained from self fertilisation of such plants are a population in which the DNA constructs behave like single Mendelian genes and are distributed according to Mendelian principles: e.g., where such a plant contains only one copy of the construct, 25% of the seeds contain two copies of the construct, 50% contain one copy and 25% contain no copy at all. Thus not all the offspring of selfed plants produce fruit and seeds according to the present invention, and those which do may themselves be either heterozygous or homozygous for the defining trait. It is convenient to maintain a stock of seed which is homozygous for the ripening-related DNA construct. All crosses of such seed stock will contain at least one copy of the construct, and self-fertilized progeny will contain two copies, i.e. be homozygous in respect of the character. Such homozygous seed stock may be conventionally used as one parent in Fl crosses to produce heterozygous seed for marketing. Such seed, and fruit derived from it, form further aspects of our invention. We further provide a method of producing FI hybrid plants expressing a ripening-related DNA sequence which comprises crossing two parent lines, at least one of which is homozygous for a ripening-related DNA construct. A process of producing FI hybrid seed comprises producing a plant capable of bearing genetically modified fruit homozygous for a ripening-related DNA construct, crossing such a plant with a second homozygous variety, and recovering Fl hybrid seed. It is possible according to our invention to transform two or more plants with different ripening-related DNA

constructs and to cross the progeny of the resulting lines, so as to obtain seed of plants which contain two or more constructs leading to reduced expression of two or more fruit-ripening-related proteins.

#### EXAMPLES OF THE INVENTION

The invention will now be described, by way of illustration, by the following Examples. In the Examples, reference is made to Figure 1.

#### THE DRAWING

Figure 1 is a diagrammatic map of plasmid pBINCEL.

#### EXAMPLE 1

Construction of a cDNA library of ripening genes

### 1.1 Isolation of messenger RNA

Total RNA was isolated from ripe fruit tissue (the receptacle with the achenes removed) of strawberry (*Fragaria* x *ananassa* Duch. cv. Brighton) as described by Manning K. Analytical Biochemistry 195, 45-50 (1991). Messenger RNA was isolated from total RNA by oligo(dT)-cellulose chromatography according to Bantle et al., Analytical Biochemistry 72, 413-427 (1976).

### 1.2 Synthesis of cDNA

The first and second strands of the cDNAs were synthesised from messenger RNAs using a commercial cDNA synthesis kit (RPN.1256Y: Amersham Life Sciences. Amersham, Bucks., UK), priming the first strand cDNA synthesis with oligo-dT.

### 1.3 Cloning into vector

Double stranded cDNAs were cloned into the \(\lambda\)gt10 vector using the BRL cloning system (8287SA: Bethseda Research Laboratories, Paisley, Renfrewshire, UK) essentially as follows. Internal EcoRI sites of the cDNAs were methylated using EcoRI methylase. The DNA termini were repaired with T4 DNA polymerase and phosphorylated EcoRI linkers ligated to the cDNA with T4 ligase. Excess linkers were digested and removed by column chromatography on DEAE-Sephadex. The purified double stranded cDNAs with EcoRI termini were ligated into \(\lambda\)gt10 vector DNA digested with EcoRI and dephosphorylated. Vector DNA was then packaged using an in vitro packaging extract (Promega Corporation, Southampton, UK). Recombinant bacteriophage were mixed with plating bacteria (E. coli C600 hflA 150) as described in the BRL protocol to determine titre, for library screening and subsequent amplification.

# 1.4 Screening of the cDNA library from ripe strawberry

The unamplified cDNA library from ripe strawberry was differentially screened using cDNA from fruit receptacle tissue at the ripe and white stages of ripeness. A proportion of the library was plated at low density and duplicate plaque lifts made on to Hybond N nylon filters (Amersham) according to the manufacturer's instructions. One filter was hybridised to ripe cDNA from white fruit and the duplicate filter hybridised to ripe cDNA. Hybridisations were at high stringency using digoxigenin as a non-radioactive label (Boehringer Mannheim, Lewes, Sussex, UK). Plaques hybridising preferentially to ripe cDNA were picked and replated at low density for a second round of selection by differential screening. Single plaques from the second screening were picked and numbered as ripening-enhanced clones.

# 1.5 Characterisation of the ripe cDNA library and ripening-enhanced clones

The ripe cDNA library was prepared with an efficiency of 3.03x 106 plaque-forming units per microgram of cDNA. The size of the cDNA inserts in this library ranged from approximately 0.24 to 6 kbp with a mean insert size of approximately 1.4 kbp.

From the 1343 plaques used in the first screen, 83 putative ripening clones were obtained. Of these, 48 were pure clones with single inserts, the remainder being impure and having multiple inserts.

The 48 clones with single inserts were partially sequenced using the DyeDeoxy (Trade Mark) Terminator Cycle Sequencing Kit (Applied Biosystems, Warrington, Cheshire, UK) with forward and reverse primers specific for the  $\lambda$ gt10 vector. Improved sequence data were obtained for clones with multiple inserts and clones with single inserts that did not produce good sequence data by subcloning into the phagemid vector pBK-CMV (Stratagene) vector for sequencing. From the sequenced clones, the following twenty-seven ripening-related clones were selected. Comparison of these sequences with sequences in the EMBL database using GCG ("Winconsin") software has identified homologies for the clones of sequences 1 to 16 listed in the following table 1.

Sequence ID	Homology/Identity	Clone number
NO		
. 1	O-methyl transferase	1
2	acyl carrier protein (ACP)	3
3	elongation factor	33a
4	auxin-induced gene	33b
5	cysteine(thiol) proteinase	93c
6	cellulase	97
7	starch phosphorylase	6ab

8	pyruvate decarboxylase	16bc
9	chalcone reductase	31c
10	protein kinase	75b
11	auxin-related gene	6lc
12	sucrose transporter	110ab
13	meristem pattern gene	26
14	transcribed sequence, T45086	13
- 15	transcribed sequence, L36159	56
16	transcribed sequence, T45902	61b
17	StrawRipe A	10

# 1.6 Expression of ripening enhanced clones

RNA was extracted from strawberry fruit during normal development and analysed by Northern blotting using standard procedures. The level of messenger RNA corresponding to the expression of O-methyl transferase, cysteine proteinase, acyl carrier protein and auxin induced gene were monitored in the receptacle at various time points between pollination and the overripe stage, between Day 1 and Day 19, and then at the stages of Turning, Orange, Ripe and Overripe. Messenger RNA for O-methyl transferase appeared at Day 19,

through to Overripe and was highest at Orange and Ripe. The messenger RNA for cysteine proteinase was low up to day 19, and then increased between the Turning and Overripe stages. The messenger RNA for Acyl carrier protein was low up to Day 19, and increased for Turning, Orange and Ripe. The messenger RNA for Auxin induced gene appeared around Day 16, and was highest between the Turning and Overripe Stages.

The data provide evidence that O-methyl transferase, cysteine proteinase, acyl carrier protein and auxin induced gene are involved in the ripening process in normal fruit development.

### **EXAMPLE 2**

Construction of antisense RNA vectors with the CaMV35S promoter

A vector is constructed using the sequences corresponding to a fragment of one of the sequences 1 to 38, more especially one of the sequences 1 to 27. This fragment is synthesised by the polymerase chain reaction using synthetic primers. The ends of the fragment are made flush with T4 polymerase and it is cloned into a derivative of the pBINPLUS vector (van Engelen et al., Transgenic Research 4, 288-290 (1995)) containing the cauliflower mosaic virus (CaMV) 35S promoter-nopaline synthase (nos) 3' terminator cassette inserted into the HindIII/EcoRI site. For example, in this way, the plasmid pBINCEL is obtained which is derived from pBINPLUS and which contains cellulase cDNA in either the sense or antisense orientation. A diagrammatic map of the plasmid pBINCEL is given in Figure 1. In one particular experiment, an antisense extended sequence comprising the cellulase of SEQ ID:6: with the addition of a polyA tail of 17 bases was inserted to give a pBINCEL antisense cellulase vector.

Alternatively a vector is constructed using a restriction fragment obtained from a strawberry ripening-related clone. The fragment is blunt ended with T4 polymerase and is cloned into a derivative of the pBINPLUS vector.

After synthesis of the vector, the structure and orientation of the sequences are confirmed by DNA sequence analysis.

#### **EXAMPLE 3**

Construction of antisense RNA vectors with a fruit enhanced promoter.

The fragment of the ripening-related cDNA that was described in Example 2 is also cloned into the vector pJR3 pJR3 is a Bin 19 based vector, which permits the expression of the antisense RNA under the control of the tomato polygalacturonase (PG) promoter. This vector includes approximately 5 kb of promoter sequence and 1.8 kb of 3' sequence from the PG promoter separated by a multiple cloning site

After synthesis, vectors with the correct orientation of the ripening-related sequences are identified by DNA sequence analysis.

Alternative fruit enhanced promoters (E8, 2A11 or any strawberry promoter) are substituted for the polygalactonurase promoter in pJR3 or for the CaMV 35S promoter in the modified pBINPLUS vector described in Example 2 to give alternative patterns of expression.

### **EXAMPLE 4**

Construction of truncated sense RNA vectors with the CaMV 35S promoter

The fragment of the ripening-related cDNA that was described in Example 2 is also cloned into the vectors described in Example 2 in the sense orientation.

After synthesis, the vectors with the sense orientation of the phytoene synthase sequence are identified by DNA sequence analysis.

#### **EXAMPLE 5**

Construction of truncated sense RNA vectors with fruit-enhanced promoter.

The fragment of the ripening-related cDNA that was described in Example 3 is, also cloned into the vectors described in Example 3 in the sense orientation.

After synthesis, the vectors with the sense orientation of the ripening-related sequence are identified by DNA sequence analysis.

### **EXAMPLE 6**

Construction of an over-expression vector using the CaMV35S promoter

The complete sequence of a ripening-related cDNA containing a full open-reading frame is inserted into the vectors described in Example 2.

#### **EXAMPLE 7**

Construction of an over-expression vector using a fruit-enhanced promoter

The complete sequence of a ripening-related cDNA containing a full open-reading frame is inserted into the vectors described in Example 3 (pJR3 or alternatives with different promoters).

#### **EXAMPLE 8**

### Generation of transformed plants

Vectors are transferred to Agrobacterium tumefaciens EHA105 (a kanamycin sensitive strain of an organism widely available to plant biotechnologists. Hood et al., Transgenic Research 2, 208-218 (1990)) and are used to transform strawberry plants. Strawberry explants infected with Agrobacterium are grown on regeneration medium normally containing 100 mg/l kanamycin. After three weeks, the explants are transferred to regeneration medium without kanamycin. At 4 to 6 weeks, putatively transformed shoots are cultured on propagation medium for two weeks and then transformants are selected on medium containing 25 mg/l kanamycin. Regenerated plants containing the transgene are selected and grown to maturity. Ripening fruit are analyzed for modifications to their ripening characteristics.

For example, transformed plants were produced in this way using the pBINCEL antisense cellulase fragment of Example 2. The presence of the transgene in the putative strawberry transformant was verified by PCR using genomic DNA from the transformant as template and primers from the 35S promoter and from the cellulase strand. The PCR products were separated by agarose gel electrophoresis and a fragment of ~1400 base pairs was obtained that was identical in size to the PCR product obtained using the pBINCEL antisense cellulase vector DNA as template.

The following sequences have been edited to remove vector bases and polyA regions, as appropriate

### (2) INFORMATION FOR SEQ ID NO:7:

(i) SEQUENCE CHARACTERISTICS:

(A) LENGTH: 585

(B) TYPE cDNA

(C) STRANDEDNESS: Single

(D) TOPOLOGY: Linear

(ix) FEATURES

(D) OTHER INFORMATION: Starch phosphorylase

### (xi) SEQUENCE DESCRIPTION: SEQ ID:7:

#### CLAIMS

- A vector for use in the genetic transformation of strawberry cells, comprising a promoter sequence, a regulation sequence and a transcription termination sequence, in which the regulation sequence comprises the coding region, or a fragment of at least 10 bases thereof, of a strawberry protein selected from O-methyl transferase, acyl carrier protein (ACP), elongation factor, auxin-induced gene, cysteine(thiol) proteinase, cellulase, starch phosphorylase, pyruvate decarboxylase, chalcone reductase, protein kinase, auxin-related gene, sucrose transporter, meristem pattern gene, or selected from a strawberry protein with homology to transcribed sequence, T45086, transcribed sequence accession number L36159 or transcribed sequence accession number T45902, or selected from a strawberry protein of unknown homology encoded by one of the StrawRipe sequences A to K.
- 2. A vector according to claim 1, wherein the regulation sequence comprises a sequence selected from SEQ ID NO:1: to SEQ ID NO:38:, and fragments thereof with at least 10 bases.
- 3. A vector according to claim 1 or 2, wherein the regulation sequence is aligned for antisense expression.
- A vector according to claim 1 or 2, wherein the regulation sequence is aligned for sense expression.
- 5. A vector according to any preceding claim, wherein the regulation sequence fragment comprises at least 35 bases.
- 6. A method for genetic modification of a strawberry comprising inserting a vector as claimed in any preceding claim into the genome of a strawberry plant.

- Propagation material for a strawberry plant which plant is progeny of a strawberry plant which has been modified by a method according to claim 6.
- 8. Strawberry fruit of a strawberry plant grown from propagating material according to claim 7.
- 9. Strawberry fruit according to claim 8, with regulated ripening in comparison with unmodified fruit.
- 10. A gene regulation sequence selected from SEQ ID NO:1: to SEQ ID NO:38:, and fragments thereof with at least 10 bases.

Box 1 Observations where certain claims were found unsearchable (Continuation of item 1 of first sheet)
This International Search Report has not been established in respect of certain claims under Article 17(2)(a) for the following reasons:
Claims Nos.: because they relate to subject matter not required to be searched by this Authority, namely:
2. X Claims Nos.:  1-10  because they relate to parts of the International Application that do not comply with the prescribed requirements to such an extent that no meaningful International Search can be carried out, specifically:  Claims 1-10 of invention 1 have been searched keeping Seq.Id.No. 1 and 28 as subject matter, since the concept defined as "0-methyl-transferase" is vague and too broad.
3. Claims Nos.: because they are dependent claims and are not drafted in accordance with the second and third sentences of Rule 6.4(a).
Box II Observations where unity of invention is lacking (Continuation of item 2 of first sheet)
This International Searching Authority found multiple inventions in this international application, as follows:
27 inventions * see continuation-sheets PCT/ISA/210 *
As all required additional search fees were timely paid by the applicant, this International Search Report covers all searchable claims.
2. As all searchable claims could be searched without effort justifying an additional fee, this Authority did not invite payment of any additional fee.
3. As only some of the required additional search fees were timely paid by the applicant, this International Search Report covers only those claims for which fees were paid, specifically claims Nos.:
4. X No required additional search fees were timely paid by the applicant. Consequently, this International Search Report is restricted to the invention first mentioned in the claims; it is covered by claims Nos.:
1-10 (partially)
Remark on Protest  The additional search fees were accompanied by the applicant's protest.  No protest accompanied the payment of additional search fees.

Form PCT/ISA/210 (continuation of first sheet (1)) (July 1992)

### INTERNATIONAL SEARCH REPORT

International Application No. PCT/GB 97/00178

#### FURTHER INFORMATION CONTINUED FROM PCT/ISA/210

- 1. Claims 1-10 (partially):

  A vectorfor use in genetic transformation of strawberry cells, comprising a promoter sequence, a regulation sequence and a transcription termination sequence, in which the regulation sequence comprises the coding region or a fragment thereof, of a strawberry 0-methyl-transferase and its use.
- 2. Claims 1-10 (partially): A vector for use in genetic transformation of strawberry cells, comprising a promoter sequence, a regulation sequence and a transcription termination sequence, in which the regulation sequence comprises the coding region or a fragment thereof, of a strawberry acyl-carrier protein (ACP) and its use.
- 3. Claims 1-10 (partially):

  A vector for use in genetic transformation of strawberry cells, comprising a promoter sequence, a regulation sequence and a transcription termination sequence, in which the regulation sequence comprises the coding region or a fragment thereof, of a strawberry elongation factor and its use.
- 4. Claims 1-10 (partially): A vector for use in genetic transformation of strawberry cells, comprising a promoter sequence, a regulation sequence and a transcription termination sequence, in which the regulation sequence comprises the coding region or a fragment thereof, of a strawberry auxin-induced gene and its use.
- 5. Claims 1-10 (partially):
  A vector for use in genetic transformation of strawberry cells, comprising a promoter sequence, a regulation sequence and a transcription termination sequence, in which the regulation sequence comprises the coding region or a fragment thereof, of a strawberry cysteine(thiol) proteinase and its use.
- 6. Claims 1-10 (partially): A vector for use in genetic transformation of strawberry cells, comprising a promoter sequence, a regulation sequence and a transcription termination sequence, in which the regulation sequence comprises the coding region or a fragment thereof, of a strawberry cellulase and its use.
- 7. Claims 1-10 (partially):

  A vector for use in genetic transformation of strawberry cells, comprising a promoter sequence, a regulation sequence and a transcription termination sequence, in which the regulation sequence comprises the coding region or a fragment thereof, of a strawberry starch phosphorylase and its use.
- 8. Claims I-10 (partially):

  A vector for use in genetic transformation of strawberry cells, comprising a promoter sequence, a regulation sequence and a transcription termination sequence, in which the regulation sequence comprises the coding
  region or a fragment thereof, of a strawberry pyruvate decarboxylase and
  its use.

#### FURTHER INFORMATION CONTINUED FR M PCT/ISA/210

- 9. Claims 1-10 (partially):
  - A vector for use in genetic transformation of strawberry cells, comprising a promoter sequence, a regulation sequence and a transcription termination sequence, in which the regulation sequence comprises the coding region or a fragment thereof, of a strawberry chalcone reductase and its use.
- 10. Claims 1-10 (partially):

A vector for use in genetic transformation of strawberry cells, comprising a promoter sequence, a regulation sequence and a transcription termination sequence, in which the regulation sequence comprises the coding region or a fragment thereof, of a strawberry protein kinase and its use.

11. Claims 1-10 (partially):

A vector for use in genetic transformation of strawberry cells, comprising a promoter sequence, a regulation sequence and a transcription termination sequence, in which the regulation sequence comprises the coding region or a fragment therof, of a strawberry auxin-related general its use.

12. Claims 1-10 (partially):

A vector for use in genetic transformation of strawberry cells, comprising a promoter sequence, a regulation sequence and a transcription termination sequence, in which the regulation sequence comprises the coding region or a fragment thereof, of a strawberry sucrose transporter and its use.

13. Claims 1-10 (partially):

A vector for use in genetic transformation of strawberry cells, comprising a promoter sequence, a regulation sequence and a transcription termination sequence, in which the regulation sequence comprises the coding region or a fragment thereof, of a strawberry meristem pattern gene and its use.

14. Claims 1-10 (partially):

A vector for use in genetic transformation of strawberry cells, comprising a promoter sequence, a regulation sequence and a transcription termination sequence, in which the regulation sequence comprises the sequence or a fragment thereof, selected from a strawberry protein with homology to transcribed sequence accession number T45086 and its use.

15. Claims 1-10 (partially):

A vector for use in genetic transformation of strawberry cells, comprising a promoter sequence, a regulation sequence and a transcription termination sequence, in which the regulation sequence comprises the sequence or a fragment thereof, selected from a strawberry protein with homology to transcribed sequence accession number L36159 and its use.

16. Claims 1-10 (partially):

A vector for use in genetic transformation of strawberry cells, comprising a promoter sequence, a regulation sequence and a transcription termination sequence, in which the regulation sequence comprises the sequence or a fragment thereof, selected from a strawberry protein with homology to transcribed sequence accession number T45902 and its use.

### FURTHER INFORMATION C NTINUED FROM PCT/SA/210

- 17. Claims 1-10 (partially):

  A vector for use in genetic transformation of strawberry cells, comprising a promoter sequence, a regulation sequence and a transcription termination sequence, in which the regulation sequence comprises the sequence or a fragment thereof, selected from a strawberry protein of unknown homology encoded by the StrawRipe Sequence A and its use.
- 18. Claims 1-10 (partially):

  A vector for use in genetic transformation of strawberry cells, comprising a promoter sequence, a regulation sequence and a transcription termination sequence, in which the regulation sequence comprises the sequence or a fragment thereof, selected from a strawberry protein of unknown homology encoded by the StrawRipe Sequence B and its use.
- 19. Claims 1-10 (partially):

  A vector for use in genetic transformation of strawberry cells, comprising a promoter sequence, a regulation sequence and a transcription termination sequence, in which the regulation sequence comprises the sequence or a fragment thereof, selected from a strawberry protein of unknown homology encoded by the StrawRipe Sequence C and its use.
- 20. Claims 1-10 (partially):

  A vector for use in genetic transformation of strawberry cells, comprising a promoter sequence, a regulation sequence and a transcription termination sequence, in which the regulation sequence comprises the sequence or a fragment thereof, selected from a strawberry protein of unknown homology encoded by the StrawRipe Sequence D and its use.
- 21. Claims 1-10 (partially):

  A vector for use in genetic transformation of strawberry cells, comprising a promoter sequence, a regulation sequence and a transcriptio termination sequence, in which the regulation sequence comprises the sequence or a fragment thereof, selected from a strawberry protein of unknown homology encoded by the StrawRipe Sequence E and its use.
- 22. Claims 1-10 (partially):

  A vector for use in genetic transformation of strawberry cells, comprising a promoter sequence, a regulation sequence and a transcription termination sequence, in which the regulation sequence comprises the sequence or a fragment thereof, selected from a strawberry protein of unknown homology encoded by the StrawRipe Sequence F and its use.
- 23. Claims 1-10 (partially):

  A vector for use in genetic transformation of strawberry cells, comprising a promoter sequence, a regulation sequence and a transcription termination sequence, in which the regulation sequence comprises the sequence or a fragment therof, selected from a strawberry protein of unknown homology encoded by the StrawRipe Sequence G and its use.
- 24. Claims 1-10 (partially):

  A vector for use in genetic transformati n of strawberry cells, comprising a promoter sequence, a regulation sequence and a transcription termination sequence, in which the regulation sequence comprises the sequence or a fragment th reof, selected from a strawberry protein of unknown homol gy encoded by the StrawRipe Sequence H and its use.

International Application No. PCT/GB 97/00178

#### FURTHER INFORMATION CONTINUED FROM PCT/ISA/210

25. Claims 1-10 (partially):

A vector for use in genetic transformation of strawberry cells, comprising a promoter sequence, a regulation sequence and a transcription termination sequence, in which the regulation sequence comprises the sequence or a fragment thereof, selected from a strawberry protein of unknown homology encoded by the StrawRipe Sequence I and its use.

26. Claims 1-10 (partially):

A vector for use in genetic transformation of strawberry cells, comprising a promoter sequence, a regulation sequence and a transcription termination sequence, in which the regulation sequence comprises the sequence or a fragment thereof, selected from a strawberry protein of unknown homology encoded by the StrawRipe Sequence J and its use.

27. Claims 1-10 (partially):

A vector for use in genetic transformation of strawberry cells, comprising a promoter sequence, a regulation sequence and a transcription termination sequence, in which the regulation sequence comprises the sequence or a fragment thereof, selected from a strawberry protein of unknown homology encoded by the StrawRipe Sequence K and its use.
